Database management System 10/11/24.

II Sem (NTP) Question Paper - Oct 2022

Section - A

1) Define database and database management system

Ans: A database is an organized collection of data for one or more purposes. The data are typically organized to model relevant aspects of reality. A database management system is a software system. It allows access to the data in a database. It consists of set of interrelated data together with a set of programs to access those data.

2) What is data model? name three categories of data model

Ans: Data model can be defined as an integrated collection of concepts for describing and manipulating data, relationships b/w data, and constraints on the data in an organization.

Categories of data model are:-

- > High Level / Conceptual data model
- > Low level / Physical data model
- > Representational / Implementation data model

3) What is key attribute? Give an example

Ans: A key attribute of an entity type is one whose value uniquely identifies of that type

eg:-

4) List data types allowed in SQL

Ans: char, varchar2, number, date, timestamp, interval year, rowid, clob, blob.

5) What is transaction control language? list any two transaction control commands

Ans: A transaction is a logical unit of work that is comprised of one or more SQL statements executed by a single user. The effects of all the SQL statements that constitute a transaction can either all be committed or all rolled back.

TCL commands are:-

- > Commit
- > Rollback

6) What is concurrency control?

Ans: Concurrency control is a database management systems concept that is used to address conflicts with the simultaneous accessing or altering of data that can occur with a multi-user system.

Section - B

11) Explain the main characteristics of database approach

Ans: • Self describing nature of a database system:

A fundamental characteristic of the database approach is that the database system contains not only the database structure and constraints and also contains the definition which is stored in the system catalog.

• Insulation between Programs and Data:

The structure of data files is stored in the DBMS catalog separately from the access programs. We call this property as program data independence, which allows changing data structures and storage organization without having to change the DBMS access programs.

• Data abstraction:

The characteristic that allows program data independence and program operation independence is called data abstraction.

• Support of multiple views of the data:

Each user may see a different view of the database, which describes only the data of interest to that user.

• Sharing of data and multi-user Transaction Processing:

It means allowing a set of concurrent users to retrieve from and to update the database.

8) What is data independence? explain briefly about the types of data independence

Ans: The ability to modify a schema definition in one level without affecting schema definition in the next higher level is called "Data Independence".

Physical data independence:

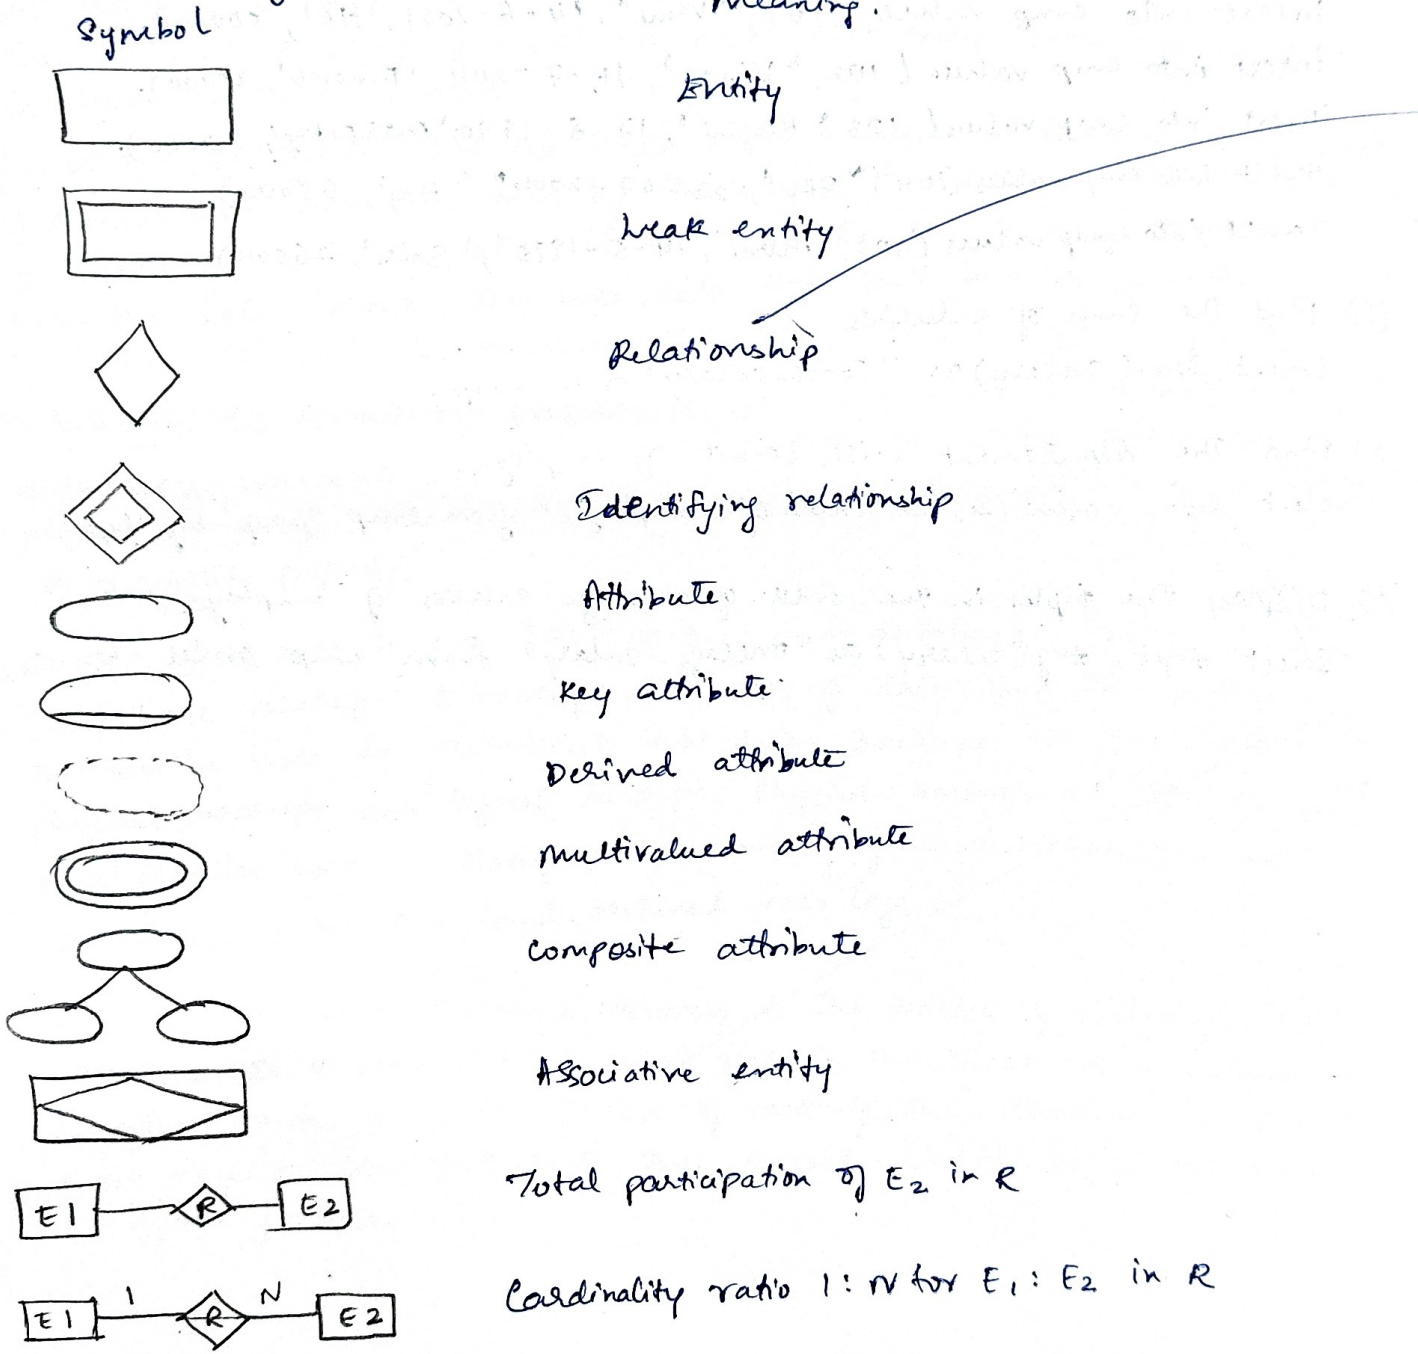

The ability to change the internal schema without having to change the conceptual schema is called physical data independence. By extension, the external schema should not change as well.

The physical data independence allows changes in the physical storage devices or organization of the files to be made without requiring changes in the conceptual view (or) any of the external views and hence in the application programs using the database. Thus, the files may migrate from one type of physical media to another of the file structure may change without any need for changes in the application programs.

Logical data independence:

The ability to change the conceptual schema without having to change the external schemas or application programs. When data is added or removed, only the view definition and the mappings need to be changed in the DBMS that support logical data independence. Logical data independence indicates that the conceptual schema can be changed without affecting the existing external schemas.

What is ER diagram? Explain different notations used in drawing ER diagram
 vs: the graphical representation of organizational system elements and the association among the elements is called ER diagram meaning.

o) Create an employee table using the following fields

Field name	Data type
EMPNO	Number
ENAME	char
DOB	Date
dept	String
Salary	Real

(a) Create the table.
create table emp (empno number(5) primary key, ename varchar2(20),
DOB date, dept varchar2(20) not null, salary number(5));

(b) Insert 5 tuples.

insert into emp values (101, "Venu", 14-6-2001, 'HR', 50000);

insert into emp values (102, "Vinas", 16-7-2011, 'Finance', 25000);

insert into emp values (103, "Ragini", 17-8-1990, 'Marketing', 30000);

insert into emp values (104, "Dev", 23-07-2004, 'HR', 65000);

insert into emp values (105, "moni", 14-5-1995, 'Sales', 76000);

(c) Find the sum of salaries

select sum(salary) as "Total-salary" from emp;

(d) Find the department wise count of employees.

select dept, count(*) as "no-of-employee" from emp group by dept;

(e) Display the tuples in the order of average salaries of employees

select dept, avg(salary) as "Average-salary" from emp order by avg

What is transaction? Explain ACID properties of a transaction

Ans: A transaction is a unit of a program execution that accesses and possibly modifies various data objects.

ACID properties:-

Atomicity: It states that all operations of the transaction take place at once. If not, the transaction is aborted.

There is no midway, i.e., the transaction cannot occur partially. Each transaction is treated as one unit and either runs to completion or is not executed at all.

Consistency: The integrity constraints are maintained so that the database is consistent before and after the transaction. The execution of a transaction will leave a database in either its prior stable state or a new stable state.

The consistent property of a database states that every transaction sees a consistent database instance.

Isolation: It shows that the data which is used at the time of execution of a transaction cannot be used by the second transaction until the first one is completed. In isolation, if the transaction T1 is being executed and using the data item x, then that data item can't be accessed by any other transaction T2 until the transaction T1 ends.

Durability: The durability property is used to indicate the performance of the database's consistent state. It states that the transaction made the permanent changes. The recovery subsystem of the DBMS has the responsibility of durability property.

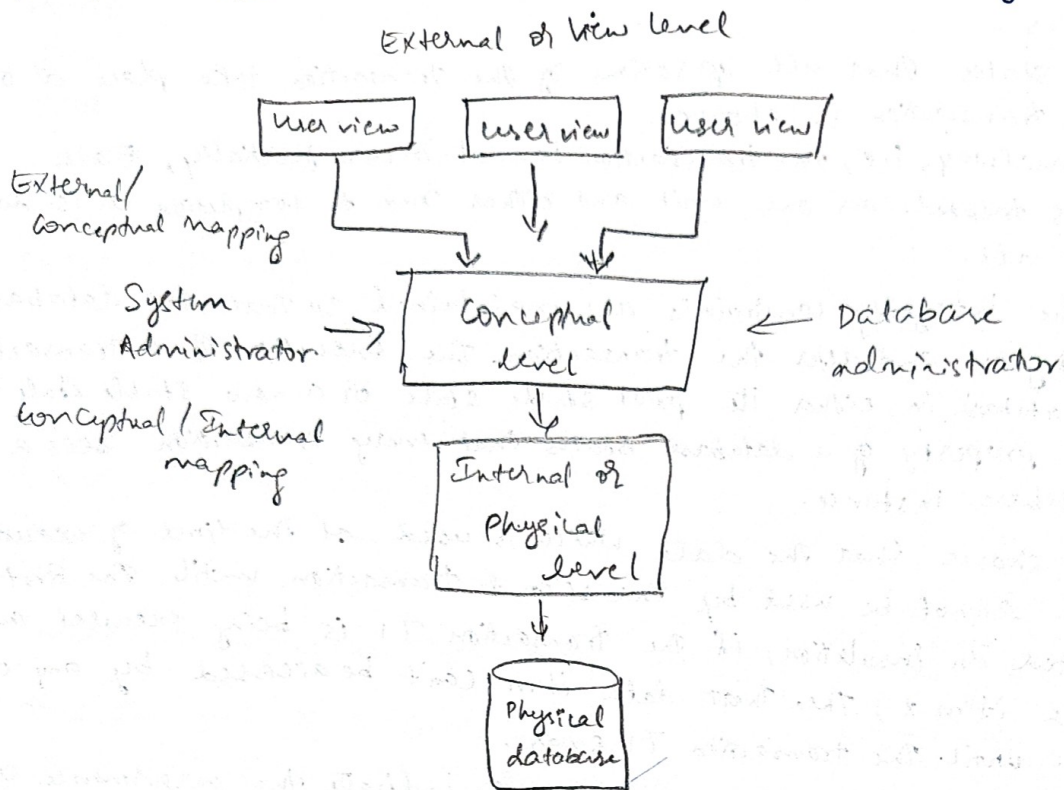

12) Write a short note on database backup and database recovery.

Ans: Database backup: A backup is a copy of data from the database that can be used to reconstruct that data. Backups can be divided into physical backups and logical backups. Physical backups are backups of the physical files used in storing and recovering your database, such as datafiles, control files, and archived redo logs.

Database recovery: Database recovery is the process of restoring the database to a correct (consistent) state in the event of a failure. In other words, it is the process of restoring the database to the most recent consistent state that existed shortly before the time of system failure.

Q1 (3) Explain Three schema architecture with a neat diagram.

Ans

External or view level : It is the user's view of the database. This level describes that part of the database that is relevant to each user. This level deals with the way in which individual users view the data. Individual users are given different views according to the user's requirements.

Conceptual level : It is the community view of the database. This level describes what data is stored in the database and the relationships among the data. The middle level in the three level architecture is the conceptual level. The conceptual level represents:

- All entities, their attributes, and their relationships
- The constraints on the data
- Semantic information about the data
- Security and integrity information

Internal or Physical level : It is the physical representation of the database on the computer. This level describes how the data is stored in the database.

The internal level is concerned with such things as:

- Storage space allocation for data and indexes
- Record descriptions for storage
- Record placement
- Data compression and data encryption techniques.

Discuss the different types of indexes

Primary index: It is an ordered file whose records are of fixed length with two fields. The first field of the index replicates the primary key of the data file in an ordered manner, and the second field of the ordered file contains a pointer that points to the data block where a record containing the key is available.

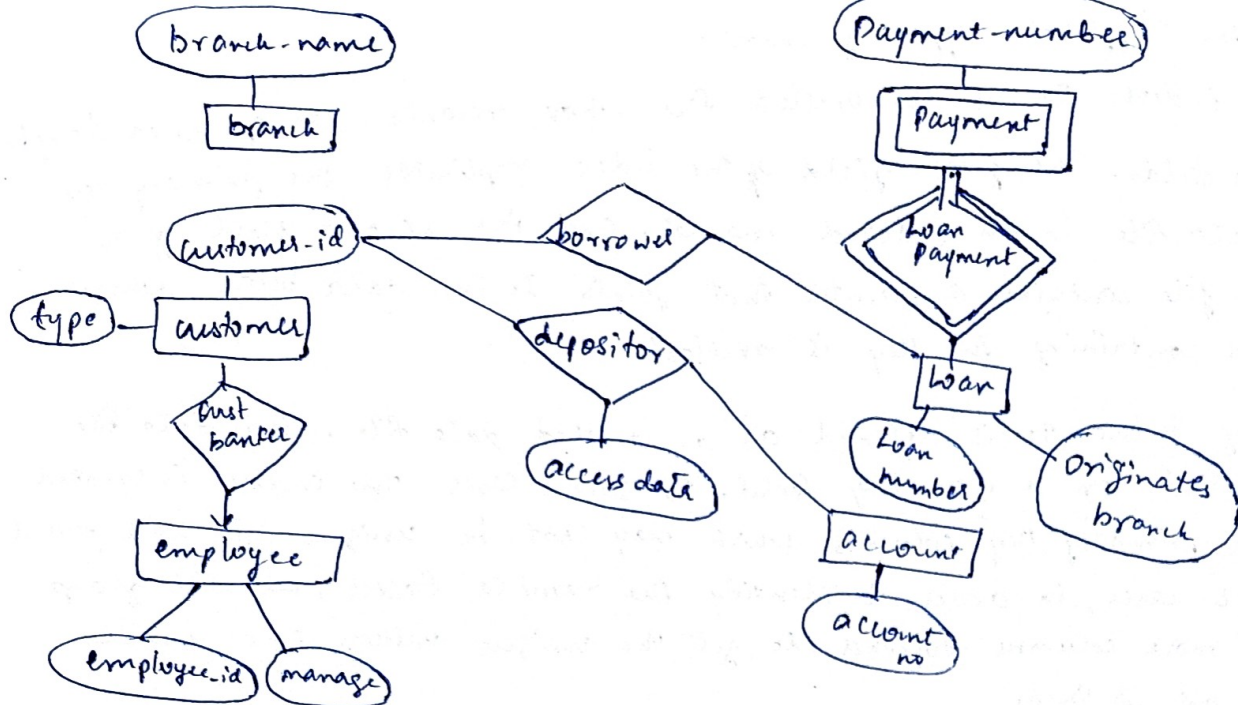

Clustering index: It is defined as an ordered data file. The data file is ordered on a non-key field. In some cases, the index is created on non-primary key columns which may not be unique for each record. In such cases, in order to identify the records faster, we will group two or more columns together to get the unique values and create index out of them.

Secondary index: The secondary index in DBMS can be generated by a field which has a unique value for each record, and it should be a candidate key. It is also known as non-clustering index. It just tells us where the data lies, i.e. it gives us a list of virtual pointers or references to the location where the data is stored.

Hash index: In a huge database structure, it is very inefficient to search all the index values and reach the desired data. Hashing is an efficient technique to directly search the location of desired data on the disk without using index structure. Data is stored at the data blocks whose address is generated by using hash function.

Bitmap indexes: A bitmap index is a special type of index designed for efficient query processing on multiple keys. It is a binary valued two-dimensional array created with an indexed column for every record in the table. They use bit arrays and answer queries by performing bitwise logical operations on these bitmaps.

(5) Draw an ER diagram for bank database with 5 entities and 5 attributes for each entity. Specify the cardinality ratio on each of the relationships existing between entities.

6) Explain different relational algebra operations.

ANS: **SELECT:** Selects all tuples that satisfy the selection condition from a relation R.

PROJECT: Produces a new relation with only some of the attributes of R₁ and removes duplicate tuples.

THETA JOIN: Produces all combinations of tuples from R₁ and R₂ that satisfy the join condition.

EQUIJOIN: Produces all the combinations of tuples from R₁ and R₂ that satisfy a join condition with only equality comparisons.

NATURAL JOIN: Same as EQUIJOIN except that the join attributes of R₂ are not included in the resulting relation; if the join attributes have the same names, they do not have to be specified at all.

UNION: Produces a relation that includes all the tuples in R₁ or R₂ or both R₁ and R₂; R₁ and R₂ must be union compatible.

INTERSECTION: Produces a relation that includes all the tuples in both R₁ and R₂; R₁ and R₂ must be union compatible.

DIFFERENCE: Produces a relation that includes all the tuples in R₁ that are not in R₂; R₁ and R₂ must be union compatible.

CARTESIAN PRODUCT: Produces a relation that has the attributes of R₁ and R₂ and includes as tuples all possible combinations of tuples from R₁ and R₂.

DIVISION: Produces relation R(x) that includes all tuples t(x) in R₁ that appear in R₁ in combination with every tuple from R₂ (y) where $z = x \div y$.

What is normalization? Differentiate b/w 3NF and BCNF

Ans: Normalization is a process that is carried out to minimize the redundancies that are present in data in relational databases. This process will mainly divide large tables into smaller tables with fewer redundancies. These smaller tables will be related to each other through well defined relationships.

3NF

- > Stands for Third normal form
- > In 3NF there should be no transitive dependency that is no non prime attribute should be transitively dependent on the candidate key.
- > 3NF can be achieved without losing any information from the old table
- > It is comparatively easier to achieve
- > The redundancy is high in 3NF

BCNF

Stands for Boyce Codd Normal Form

In BCNF, for any relation $A \rightarrow B$, A should be a super key of relation

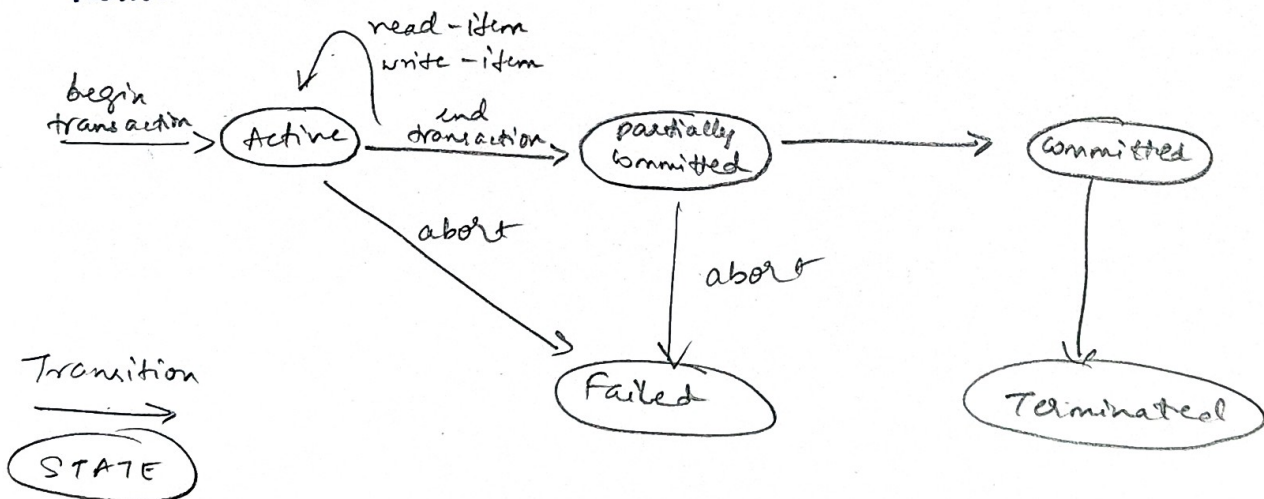

For obtaining BCNF we may lose some information from old table

It is difficult to achieve

The redundancy is comparatively low in BCNF

(8) Explain different states of transaction with a neat diagram

Ans: A transaction is any one execution of user program in a DBMS, a transaction moves through various types of execution states. Because a failure occurs, transactions are broken up into states to handle various situations

- Active state: The initial state; the transaction stays in this state while it is executing.
- Partially committed state: after the final statement has been executed
- Failed state: after the discovery that normal execution can no longer proceed
- Aborted state: after the transaction has been rolled back and the database has been restored to its state prior to the start of transaction
- Committed state: after successful completion
- The transaction has committed only if it has entered the committed state. The transaction has aborted only if it has entered the aborted state. The transaction is said to have terminated if it has either committed or aborted.
